

6 Stormwater Management

6.1 Existing Conditions

6.1.1 Site Characteristics

The project site is 15.6 acres in size consisting primarily of wooded areas. As per Technical Release 55 (TR-55) from Urban Hydrology for Small Watersheds (dated June 1986), prepared by the Soil Conservation Service, the hydraulic condition of the existing on-site vegetation is woods (fair condition).

Table 1 Existing Conditions Land Use Breakdown

Land Use	Acreage
Woods	15.6

Per the Soil Survey Report for Middlesex County, Massachusetts Interim, Fourth Edition (dated July 1995), Atlas Number 41, the majority of the project site is soil number 555 (Hydrologic Soil Group 'B') and the remaining portion of the site is soil number 46 (Hydrologic Soil Group 'D').

Runoff Curve Number (CN)

The project site consists primarily of wooded areas. The hydraulic condition of the existing on-site vegetation is woods (fair condition) based on field investigations and review of aerial maps of the site. Technical Release 55 (TR-55) from *Urban Hydrology for Small Watersheds* (dated June 1986), prepared by the Soil Conservation Service, defines woods (fair condition) as "grazed, but not burned, and some forest litter covers the soil." The on-site woods have some forest litter covering the ground and barren areas between the trees. Comments were raised regarding the land use selection of woods (fair condition). It was suggested that the land use selection should be woods (good condition). TR-55 defines woods (good condition) as "protected from grazing, and litter and brush adequately cover the soil." The proponent did not select woods (good condition) as the existing on-site land use, since the *Massachusetts Supplement for the TR-55 Hydrology Procedure* (dated April 1990), further states that land use of woods with dense underbrush should be avoided in calculating time of concentrations used to generate runoff hydrographs for the watershed because the Manning's roughness coefficient for this cover type is extrapolated from research data and does not represent typical conditions in the northeast region of the United States.

Time of Concentration

The drainage flow paths used to calculate the time of concentrations under existing and proposed conditions have been added to Figure 1, Existing Conditions Watershed Plan and Figure 3, Proposed Conditions Watershed Plan.

6.1.2 Site Surface Drainage

The hydrologic study area for this project consists of approximately 11.23 acres and includes a portion of Acorn Park Drive. The hydrologic study area is smaller in size than the total site property, since no site improvements are proposed for the portion of the property located east of Acorn Park Drive.

The site is located within the Mystic River Basin Watershed. Little River, located south of the site, flows to the northeast into Alewife Brook. Alewife Brook, located to the south of Route 2, flows to the east and then the north, where it joins with Mystic River.

More specifically, the overall Little River watershed is approximately 8.16 square miles or 5,222 acres in size. The project study area of 11.23 acres is approximately 0.2 percent (%) of the overall Little River watershed area of 5,222 acres.

The potential for flooding of downstream receiving water bodies and adjacent properties due to the proposed project is of concern by residents in the community. The intent of the proposed stormwater management systems is to mitigate for any impacts of the proposed site improvements on the overall watershed and to maintain and improve (to the extent practical) the existing conditions.

Table 2 summarizes the existing conditions drainage basin characteristics. Under Existing Conditions, the project site is divided into four (4) drainage basins (refer to Figure 1, Existing Conditions Watershed Plan).

Table 2 Existing Conditions Drainage Basin Characteristics

Drainage Basin Identification	Receiving Water bodies	Total Area (acres)	Slope of Land (%)	Hydrologic Soil Group	Land Use
Basin 1S	Swale/Little Pond	2.26	2-7%	B/D	Woods Pavement
Basin 2S	Swale/Little Pond	1.89	1-4%	B/D	Woods Pavement
Basin 3S	Wetland/Little River	2.26	0.5-3%	B/D	Woods
Basin 4S	Little River	4.82	1-9%	B/D	Woods
Total Study Area		11.23			

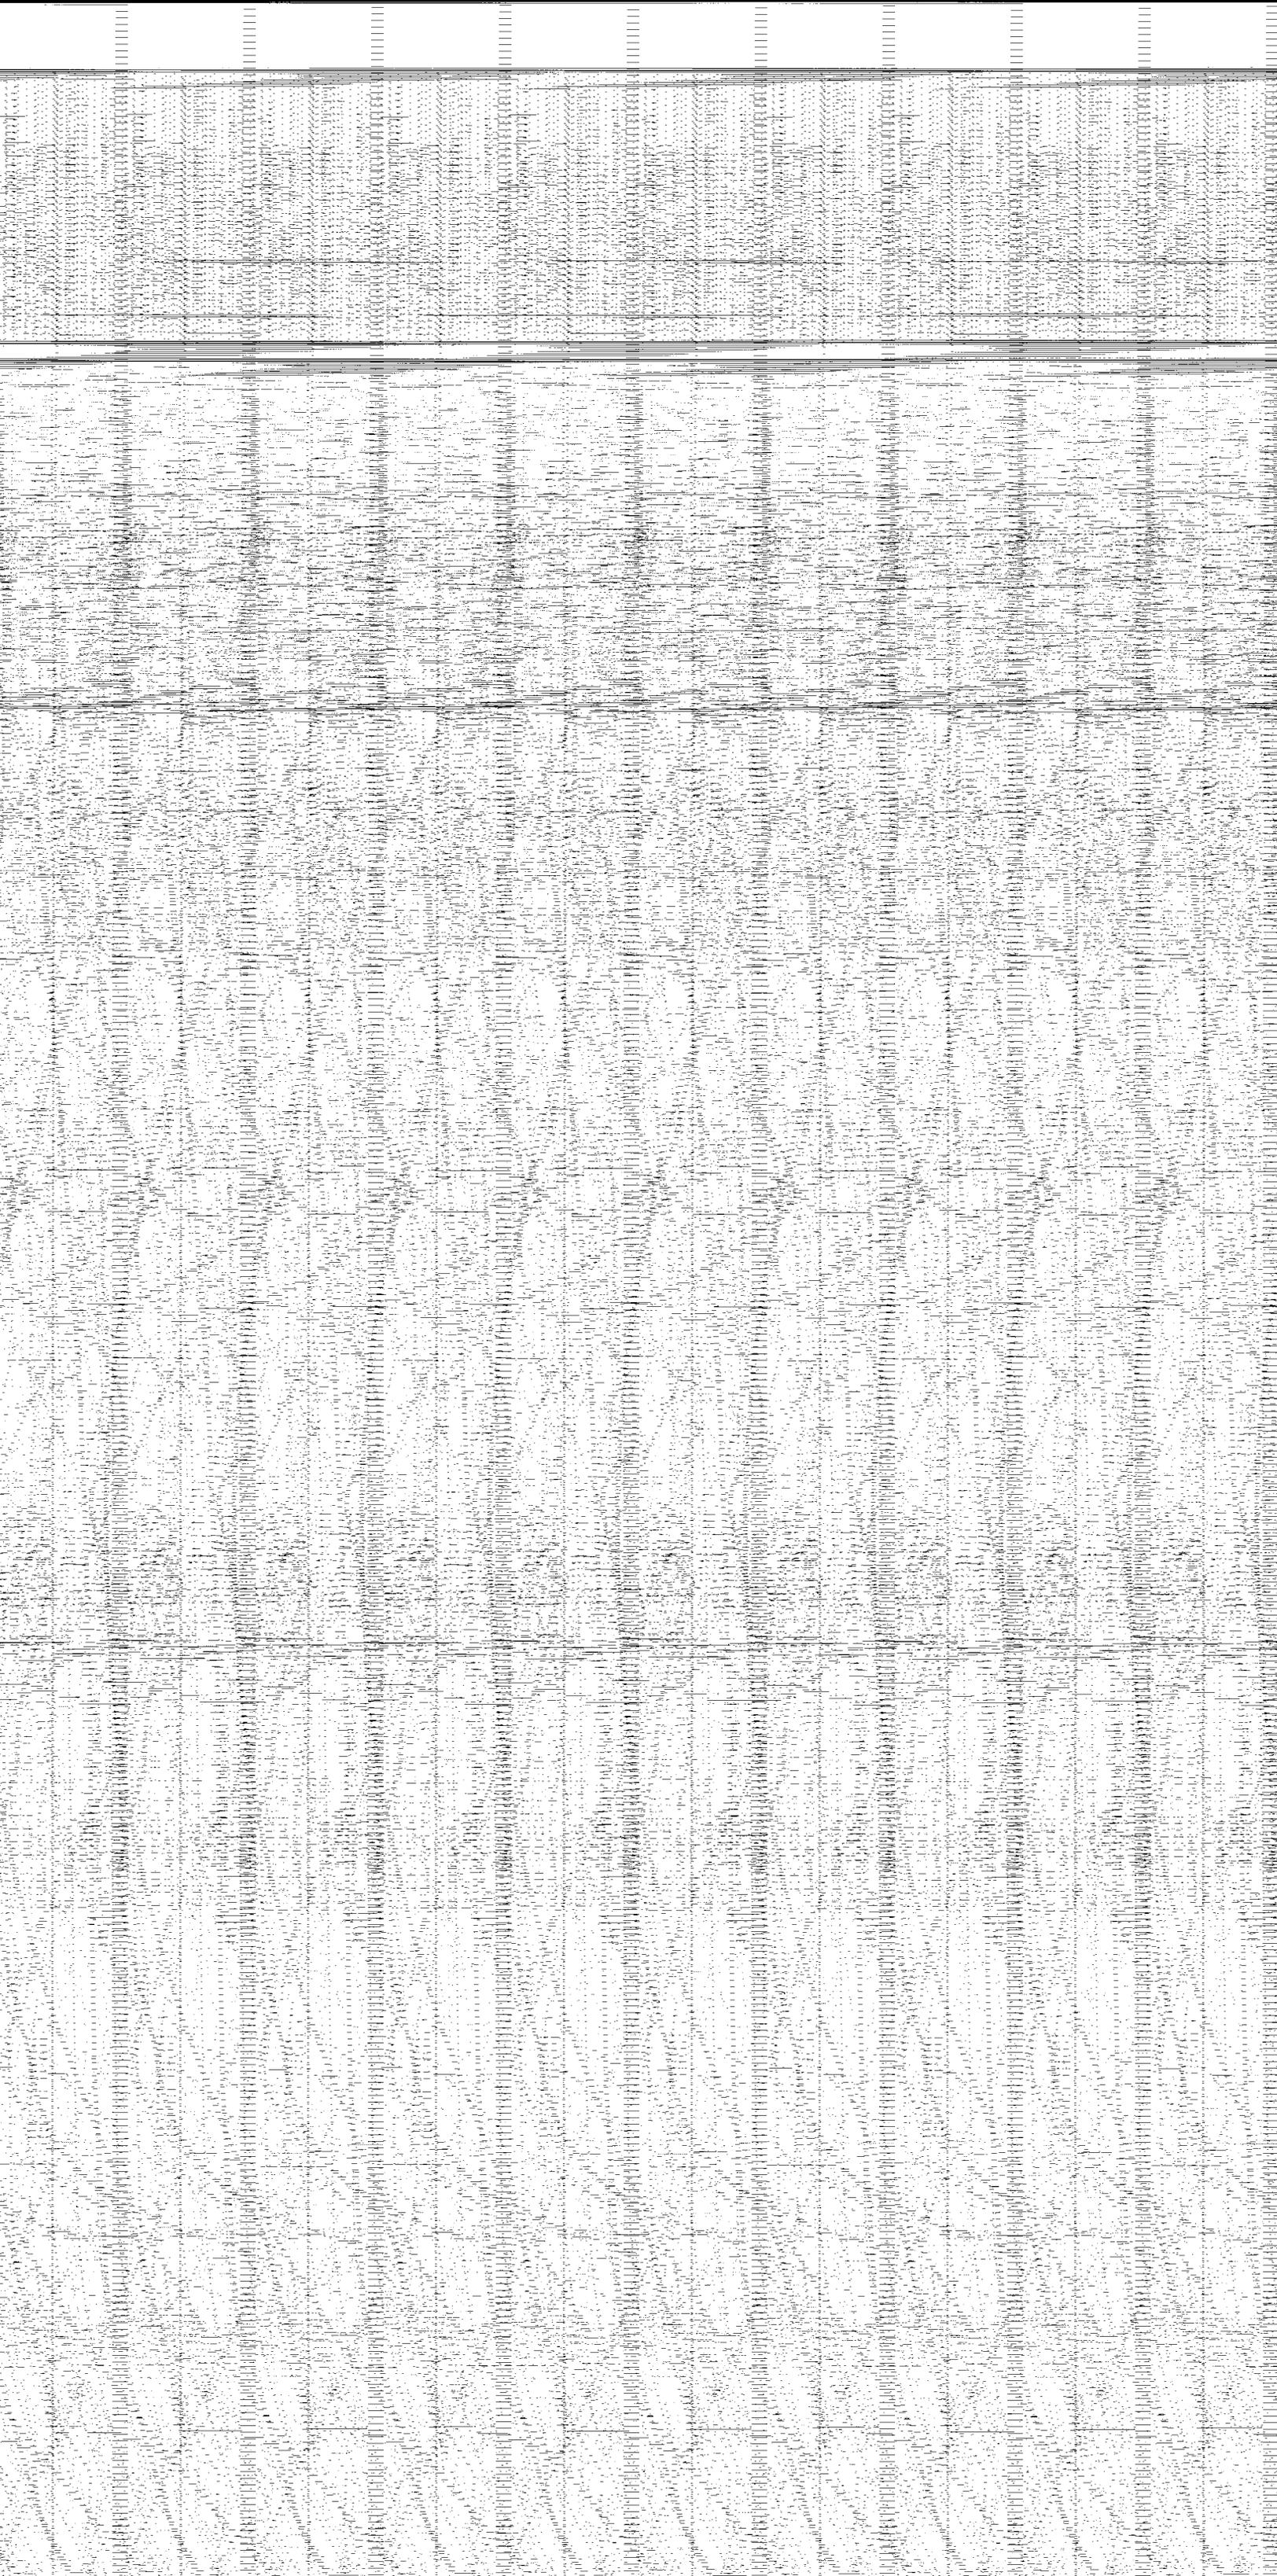

Notes: Hydrologic Soil Group 'B' refers to soils having a moderate infiltration rate.
Hydrologic Soil Group 'D' refers to soils having a slow infiltration rate (high runoff potential).

Runoff in Drainage Basin 1S sheet flows north to an existing drainage swale located along Frontage Road, which outfalls to Little Pond. Little Pond is hydraulically connected to Little River.

Runoff in Drainage Basin 2S sheet flows east to an existing drainage swale adjacent to Acorn Park Drive. During storms greater than the 2-year, 24-hour storm event, stormwater within the existing drainage swale stages to and above elevation 9.5. Once stormwater reaches elevation 9.5, it discharges over a 5-foot earthen weir to the downstream swale located along Frontage Road, which outfalls to Little Pond and ultimately to Little River.

Runoff in Drainage Basin 3S sheet flows southeasterly to an existing wetland located adjacent to Acorn Park Drive, hydraulically connected to Little River.

Runoff in Drainage Basin 4S sheet flows southwesterly to Little River.

6.1.3 Floodplain

The project site is located partially within the 100-year floodplain of Little River. The site and Little River are located within the Mystic River Basin Watershed.

According to the FIRM Flood Insurance Rate Map (Panel No. 250182 0001 B), the 100-year Flood Boundary (Zone A5) is at elevation 8.20+/- feet, NGVD for the project site.

In the case of this project, however, the proponent is anticipating a change to the mapped base flood elevation to increase to 9.8 NGVD. A FEMA analysis of this watershed is currently underway and preliminary results support the higher 100-year floodplain elevation of 9.8 NGVD.

6.2 Proposed Conditions

6.2.1 Site Surface Drainage

As previously noted, the proposed site improvements include the construction of five residential buildings, each with below grade parking, and additional surface parking. The following table summarizes the proposed condition land use breakdown for the site.

Table 3 Proposed Conditions Land Use Breakdown

Land Use	Acreage
Woods	4.45
Building	1.80
Impervious	2.81
Open Space	2.17
Total Study Area	11.23

The proposed stormwater management facilities will include two (2) existing water quality grassed or vegetated swales, two (2) surface detention basins, one (1) surface retention basin, one (1) 15' wide grass filter strip and four (4) sub-surface detention/infiltration (infiltration chambers) systems, as shown on Figure 2, Proposed Grading and Drainage Plan. One of the water quality swales is an existing swale adjacent to Acorn Park Drive which discharges to an existing swale along Frontage Road and ultimately to Little Pond. The other water quality swale outfalls to Little River.

Under proposed conditions, the study area will be divided into ten drainage basins as shown on Figure 3, Proposed Conditions Watershed Plan.

Table 5.3-4 summarizes the basin characteristics for the proposed condition drainage basins.

Table 4 Proposed Conditions Drainage Basin Characteristics

Drainage Basin Identification	Stormwater Management System/Receiving Waterbody	Total Area (acres)	Slope of Land (%)	Hydrologic Soil Group	Land Use
Basin 1S	Detention Basin 2 Swale/Little Pond	0.34	1%	B	Grass Pavement
Basin 2S	Detention Infiltration System 1	0.20	1%	B	Pavement
Basin 3S	Detention Infiltration System 2	0.96	1%	D	Roof Grass Pavement
Basin 4S	Detention Basin 1/ Wetland/Little River	1.06	2%	B/D	Roof Grass Pavement
Basin 5S	Detention Infiltration System 4	0.81	1%	B	Roof Grass Pavement
Basin 6S	Retention Basin A	1.11	1-3%	B	Roof Grass Pavement
Basin 7S	Detention Infiltration System 3	0.45	-	B	Roof
Basin 8S	Swale/ Wetland/Little River	2.29	1-3%	B/D	Woods Grass Pavement
Basin 9S	Wetland/Little River	2.76	1-2%	B/D	Woods Grass
Basin 10S	Swale/Wetland/Little River	1.27	1-7%	D	Woods Grass
Total Study Area		11.23			

Notes: Hydrologic Soil Group 'B' refers to soils having a moderate infiltration rate (medium runoff potential). Hydrologic Soil Group 'D' refers to soils having a slow infiltration rate (high runoff potential).

Runoff in Drainage Basin 1S sheet flows north across the parking lot and is collected in a drainage system which outfalls into Detention Basin 2 then is culverted into an existing drainage swale located along Frontage Road, which outfalls to Little Pond. Little Pond is hydraulically connected to Little River.

Stormwater runoff from the proposed parking area within Basin 2S will be collected and conveyed through a drainage system to a detention/infiltration system (IC-1) designed to provide peak attenuation and allow for recharge of groundwater. An 8" overflow pipe will be connected from IC-1 to a proposed catch basin located at the entrance drive.

Stormwater runoff from Building E's roof leaders and proposed parking areas in Drainage Basin 3S will be collected and conveyed through a drainage system to a detention/infiltration system (IC-2) designed to provide peak rate attenuation and allow for recharge of groundwater. An 8" overflow pipe will be connected from IC-2 to a proposed catch basin at the northern side of the parking lot.

Runoff from Building D's roof leaders and proposed parking area in Drainage Basin 4S will be collected and conveyed through a drainage system to Detention Basin 1 which provides water quality and quantity control prior to discharge to the existing wetland adjacent to Frontage Road.

Stormwater runoff from Building C's roof leaders and parking areas within Drainage Basin 5S will be collected and conveyed through a drainage system to a detention/infiltration system (IC-4), designed to provide peak rate attenuation and allow for recharge of groundwater. An 8" overflow pipe will be connected from IC-4 to a proposed catch basin located between Building E and Building D.

Stormwater runoff from the proposed parking area and Building B's roof leaders within Drainage Basin 6S will be collected and conveyed through a drainage system to Retention Basin A designed to provide peak rate attenuation and allows recharge of groundwater.

Stormwater runoff from Building A's roof leaders, within Drainage Basin 7S, will be collected into a detention/infiltration system (IC-3) designed to provide peak attenuation and allow for recharge of groundwater. An 8" overflow pipe will be connected to IC-3 and will outlet into the proposed swale at the southern side of the site.

Runoff within Drainage basin 8S sheet flows from a proposed parking lot across a grass filter strip which provides water quality control, then conveyed through a grassed swale adjacent to Acorn Park Drive which provides water quality and quantity control prior to discharging to an existing wetland.

Stormwater runoff from Drainage Basin 9S sheet flows southwesterly towards Little River.

Runoff from Drainage Basin 10S sheet flows north to an existing drainage swale located adjacent to Frontage Road, which outfalls to Little Pond which is hydraulically connected to Little River.

6.2.2 Proposed Methods of Stormwater Management

A comprehensive stormwater management plan has been prepared for the project to provide both quality and quantity controls for stormwater runoff. The stormwater management plan is in full compliance with the performance standards described in the DEP Stormwater Management Policy (1997). A copy of the DEP Stormwater Management Form for the project is included in Appendix A.

The proposed stormwater management system includes two (2) surface detention basins, one (1) surface retention basin, one (1) 15' wide grass bio-filter strip, five (5) oil/grit separators and four (4) sub-surface detention/infiltration systems. Stormwater runoff from the site will be collected and conveyed through a drainage system to the stormwater management systems. Surface runoff from paved areas to catch basins will be conveyed through oil/grit separators prior to discharging to the sub-surface detention systems.

The grass bio-filter strip provides pollutant removal through sedimentation, filtration, nutrient uptake and infiltration, and control and conveys it at low velocities to protect against erosion. The detention basins design provides for water quality treatment by allowing the settling of particulates and associated pollutants. A sediment forebay located at the inlets to the detention basins will reduce stormwater velocity and promote efficient settling of suspended solids.

Table 5 summarizes the proposed Stormwater Management System.

Table 5 Summary of Proposed Stormwater Management Systems

Stormwater Management Method	Stormwater Management Identification	Approximate Dimensions (feet by feet)	Peak Storage Volume (cubic feet)	100-year Peak Water Surface Elevation (feet) NGVD	Top of Berm Elevation (feet) NGVD
Retention Basin A	5P	50' x 220'	21,569	9.2	10.5
Detention Basin 1	6P	150' x 35'	14,199	8.3	10.2
Detention Basin 2	7P	20' x 90'	7,459	8.9	10.5
Infiltration System 1	IC-1	30' x 40'	2,868	10.1	11.5 *
Infiltration System 2	IC-2	50' x 120'	14,799	11.7	12.0 *
Infiltration System 3	IC-3	35' x 70'	5,525	11.6	12.0 *
Infiltration System 4	IC-4	85' x 70'	11,282	11.5	12.0 *

*Top of infiltration pipe

As shown in Table 5, the detention systems will contain the 100-year peak elevation, meaning that no adverse flooding impacts will occur on Acorn Park Drive, Frontage Road or abutting properties.

6.3 DEP Stormwater Management Guidelines

6.3.1 Stormwater Quality

The site is located in the Mystic River Basin Watershed to Little River, which abuts the site to the south. The project has been designed to treat 1.0 inches of runoff from all new impervious surfaces. The backup calculations are located in Appendix A. Stormwater runoff from the proposed project will be treated in water quality swales, oil/grit separators, detention basins, or a combination of these three prior to discharge. The proposed project design will inhibit transport of erosion, sediment, oil and grease, nutrients, pathogens, road salt, or debris. Therefore, no impairment of water quality will occur to impact resident and anadromous fish species that use Little Pond, Little River, or Alewife Brook.

6.3.2 Stormwater Quantity

To determine the peak rate of discharge for existing and proposed conditions, runoff hydrographs were generated for the 2-, 10-, 25- and 100-year, 24-hour storm events using the SCS TR-20 Method and Type III rainfall distribution. Under proposed conditions, the post-development runoff hydrographs were flood routed through the proposed stormwater management facilities (detention/infiltration system, detention basins and water quality swales). The pre- versus post-development peak discharge rates were compared to demonstrate that the post-development peak discharge rates will not exceed pre-development discharge rates.

Table 6 summarizes the total rainfall amounts input into the HydroCAD© analyses for the 2-, 10-, 25- and 100-year storm events.

Table 6 Total Rainfall versus Storm Frequency

Storm Event	Duration (hours)	Total Rainfall Amounts (inches)
2-year	24	3.3
10-year	24	4.6
25-year	24	5.4
100-year	24	6.6

The rainfall amounts summarized in Table 6 are based on review of the precipitation values for Massachusetts contained in the Massachusetts Supplement for the TR-55 Hydrology Procedure (210-EFM, Amend. MA1 April 1990), Technical Publication, TP-40.

Table 7 summarizes the pre- and post-development discharge rates determined in the hydrologic/hydraulic analyses performed for the study area. The backup data for the analyses is contained in Appendix A.

Table 7 Pre- versus Post -Development Peak Discharge Rates

Storm Event	Pre-Development Rate (CFS)	Post-Development Rate (CFS)
2-Year, 24-Hour	6.2	6.1
10-Year, 24-Hour	13.1	11.7
25-Year, 24-Hour	17.9	15.8
100-Year, 24-Hour	25.5	22.7

The pre- versus post-development peak discharge rates were compared to demonstrate that the post-development peak discharge rates will not exceed pre-development discharge rates.

As shown in Table 7, the post-development discharge rate for each storm event is less than the peak discharge rate under pre-development conditions. Therefore, the proposed project meets DEP Stormwater Management Standard No. 2 – Peak Discharge Rates, meaning that there will be no adverse impacts to downstream waterbodies, Acorn Park Drive, Frontage Road or abutting properties.

6.3.3 Groundwater Recharge

Under proposed conditions, impervious surfaces (i.e., roof tops, pavement) will be added to the site. The additional stormwater runoff and loss of groundwater recharge due to the increase in impervious surfaces will be mitigated in accordance with DEP Stormwater Management Standard No. 3 – Groundwater Recharge by infiltrating the roof runoff from the buildings and a portion of the parking area.

According to the Middlesex Soils Survey, the project site is located within Hydrological Soil Groups 'B' and 'D'. Based on the DEP Stormwater Management Guidelines, the required groundwater recharge volumes for Hydrological Soil Groups 'B' and 'D' are as follows:

Hydrological Soil Group 'B': 0.25 inches of runoff multiplied by the total impervious area overlying Type 'B' soils.

Hydrological Soil Group 'D': Waived (Because the soils are not conducive to infiltration).

On the basis of these recharge volumes, the required groundwater recharge volume (based on the most conservative Type 'B' soil classification) is 0.08 acre-feet. (3.866 ac. x 0.25")

The proposed detention/infiltration system will infiltrate 0.10 acre-feet of stormwater runoff, thereby exceeding the required DEP recharge standard. Backup calculations are included in Appendix A.

Groundwater elevations within the vicinity of the proposed swales, detention basin and infiltration system were based on borings performed on-site. The boring logs are included in a report entitled, Hydrogeological Report, Frontage Road Office Center (March 6, 2001) prepared by McPhail Associates, Inc. and Epsilon Associates, Inc. In addition, the observed high water table elevation below the proposed detention/infiltration systems was based on site specific groundwater monitoring described in the Groundwater Monitoring Report (dated August 28, 2001) prepared by McPhail Associates, Inc. The observed high groundwater elevations and the elevations at the bottom of the systems are listed below in Table 8. As shown, there is no groundwater interception through the bottom of the stormwater management systems.

Table 8 Observed High Groundwater Elevations

Stormwater Management System	Bottom Elevation	Groundwater Elevation
Retention Basin A	7.0	4.7
Detention Basin 1	6.0	4.2
Detention Basin 2	7.0	5.5
Infiltration System 1	8.5	6.0
Infiltration System 2	8.0	6.0
Infiltration System 3	8.5	7.5
Infiltration System 4	8.0	4.5

During final design of the project, additional groundwater data will be collected to ensure that acceptable separation distances will be maintained.

Percolation tests will be performed near the proposed detention/infiltration system and detention basin as part of the final design. The current design uses a constant infiltration rate of 0.52 inches per hour based on hydrologic soil properties classified by United States Department of Agriculture soil texture for Hydrologic Soil Type 'B'. Given the current understanding of the soils on-site, this rate is considered a conservative estimate of the actual infiltration rate.

6.3.4 TSS Removal Rates

To achieve the required 80 percent total suspended solids (TSS) removal (Standard No. 4), the stormwater management system has been designed to incorporate Best Management Practices (BMP) as outlined in the DEP Stormwater Management Handbook. These include street sweeping (10% removal), deep sump and hooded

catchbasins (25% removal), dry detention basin (70% removal), grassed water quality swales (70% removal) and oil/grit separators (25% removal). The proposed BMPs are described below.

Street Sweeping. The proposed design incorporates street sweeping as a BMP to control the amount of sediment that enters the drainage system. Street sweeping will occur at least two times a year, once coinciding with the end of the winter sanding season and once during the late fall. Efforts will also be made to provide street sweeping immediately following winter snowmelt when road sand and other sediments have accumulated.

Deep Sump Catchbasins. The on-site drainage collection system will incorporate deep sump catchbasins, which will serve to trap sediment and floatables. Sumps will be four-feet deep, and hoods will be provided with vacuum-breaks to avoid siphoning of floatables out of the catchbasin.

Grassed Bio-Filter Strip. A grassed 15 foot wide grassed bio-filter strip will be utilized at the southern side of the site. The strip is planted with vegetation and materials to help capture pollutants, develop nitrogen uptake and to decrease runoff velocity prior to discharging into adjacent wetlands. According to the DEP Stormwater Guidelines, swales capture approximately 70 percent of TSS.

Detention Basins. The detention basins will include a sediment forebay to assist in settling of suspended solids. According to the DEP Stormwater Guidelines, detention basins capture approximately 70 percent of TSS.

Oil/Grit Separators. The proposed design of the on-site drainage system will incorporate oil/grit separators prior to discharging to the underground detention system. According to DEP Stormwater Guidelines, oil/grit separators are similar to deep sump catch basins and capture 25% of TSS.

Underground Infiltration System. Each system consists of a series of perforated pipes surrounded with drain rock and filter fabric. The pavement runoff is directed through the catchbasins and an oil/grit separator prior to discharging into the infiltration system. The infiltration systems used for this project capture approximately 70% of TSS.

As shown in Table 9, the incorporation of these BMP measures will remove approximately 80 % of the TSS in the water column from the proposed impervious surfaces. The composite TSS removal rate of at least 80% was obtained by calculating the TSS removal rate percentage per proposed BMPs "treatment train" for each basin and multiplying by the prorated contributing impervious area.

Table 9 Total Suspended Solids Removal Rate

BMP Methods (TSS Removal Rate%)	Composite TSS Removal Rate Percentage (%)⁽¹⁾
Street Sweeping (10%)/ Deep Sump Catchbasins (25%)/ Grassed Bio-Filter Strip (70%)	80.0
Street Sweeping (10%)/ Deep Sump Catchbasins (25%)/ Detention Basin (70%)	80.0
Street Sweeping (10%)/ Deep Sump Catchbasins (25%)/ Oil/Grit Separators (25%)/ Infiltration System (70%)	<u>85.0</u>
CUMULATIVE TOTAL	82.0

Notes: ¹Refer to TSS Removal Calculation Worksheets for each basin within Appendix A.

6.3.5 Erosion and Sedimentation Controls

The following erosion and sedimentation control devices will be implemented to prevent erosion both during and after construction.

- ◆ Initially an erosion control barrier, consisting of a silt fence staked by hay bales, will be installed at the limit of work.
- ◆ The temporary sedimentation basins will be constructed in the location of the permanent water quality swales and the detention basin. However, the detention/infiltration system will not be used as a temporary sediment trap for construction utilities. A temporary sedimentation basin will be located upgradient of the detention/infiltration system. The temporary sedimentation basins will be cleaned prior to final grading and stabilization of the water quality swales and the detention basin. The temporary sedimentation basin located upgradient of the detention/infiltration system will be removed.
- ◆ Construction entrance apron pads will be constructed at the main site access drive to prevent the tracking of sediment on vehicle tires from transport onto adjacent streets.
- ◆ Silt bags will be installed at all existing catchbasin structures to prevent silt from entering the existing drainage lines.

- ◆ During construction, cut and fill slopes will be stabilized immediately upon completion with loam, hydro-seeding and erosion control blankets.
- ◆ All drainage outfalls will include rip-rap aprons in order to mitigate discharge velocities and minimize erosion potential.
- ◆ Temporary haybales will be placed around all new catchbasins, and maintained throughout the duration of construction to prevent silt material from entering the drainage system.

6.3.6 Operation and Maintenance Plan

An Operation and Maintenance Plan for the project site has been prepared in accordance with DEP Stormwater Management Standard No. 9.

The Stormwater Management System will be the overall responsibility of the Owner. The General Contractor (under Contract with the Owner) will appoint a Project Manager who will be responsible during construction. A Facility Manager, hired by the owner, will be responsible after construction completion.

Short-term impacts may occur during construction activities. To minimize these impacts, a comprehensive soil and erosion control plan will be implemented prior to any project construction activities. The primary items of the soil and erosion control plan are outlined below.

- ◆ Erosion and sedimentation control devices will be installed along the perimeter of the proposed work area. In addition to providing for sediment deposition and reducing runoff during storm events, the barrier will limit work areas for equipment operators.
- ◆ Erosion and sedimentation control devices will be inspected daily during periods of active construction and bi-weekly during the remainder of the construction period. During the construction activities, erosion control devices will be placed at catchbasins to prevent sediment from reaching discharge points.
- ◆ Heavy equipment will not be allowed to operate on the surface location where the detention/infiltration system is planned because soil compaction could adversely affect the long-term performance of the system. Diversion berms or staked and lined haybales will be used around the perimeter of the system during its construction. Manual removal or light earth-moving equipment will be used for excavation and construction of the detention/infiltration system. Excavated material from this area will be located downgradient to prevent redeposition of this material into the system during runoff events.
- ◆ Stockpiles of cut trees and excavated and/or fill materials will be consolidated outside of wetland resources areas. If a temporary stockpile area is necessary within

the 100-foot Buffer Zone, it will be protected with appropriate erosion controls, such as hay mulch, grass seed, haybale barriers, or a combination of the above to minimize erosion. At the conclusion of the project, stockpiles will be removed from the 100-foot Buffer Zone, original elevations will be restored, and the areas stabilized.

- ◆ If necessary, temporary drainage swales will be used to divert stormwater to temporary sedimentation basins. The swales will be constructed with hay bale check dams to prevent erosion. The check dams will be spaced at intervals no greater than 100 feet. The temporary basin will be constructed where the permanent basin has been designed. The basins will be cleaned out prior to final grading and stabilization.
- ◆ During construction, disturbed areas will be kept to a minimum, and vegetative stabilization of these areas will occur as soon as possible. Areas that cannot be restored or stabilized immediately will be mulched to prevent any potential erosion or sedimentation.
- ◆ Temporary seeding, mulching, or other suitable stabilization measures will be used to protect exposed critical areas, should unprotected soils remain exposed for prolonged periods. Following construction, and once disturbed areas have been stabilized, erosion controls will be removed.

The schedule for inspection and maintenance during and after construction is described below.

Schedule for Inspection and Maintenance during construction:

- ◆ *Erosion Control Barrier:* The erosion control barrier will be installed prior to commencement of construction and inspected weekly, prior to storm events and immediately after storm events to ensure its integrity. The erosion control barrier will be repaired as necessary to prevent erosion.
- ◆ *Construction Entrance Aprons:* The construction entrance aprons will be installed prior to commencement of construction and inspected weekly. The construction entrance aprons will be replaced when debris becomes noticeable on the existing pavement surfaces opposite the construction side.
- ◆ *Slope Stabilization:* Slope stabilization controls will be installed immediately upon obtaining final grades as shown on the project plans. Areas in failure will be re-graded to final grade and stabilized as necessary.
- ◆ *Baled Hay Silt Barrier around Catchbasins:* The catchbasin barriers will be installed immediately after installation of catchbasin grates and will be inspected weekly, prior to storm events and immediately after storm events. Catchbasin barriers will be replaced in areas of failure.

- ◆ *Riprap Slope Protection:* Slopes requiring riprap protection will be installed to obtain final grade.
- ◆ *Infiltration System:* These systems will not be constructed until after the site has been stabilized and will not be used as a temporary sediment trap during construction. Diversion berms or staked and lined haybales will be utilized around the perimeter of the system during its construction. Manual removal or light earth-moving equipment will be used for excavation and construction of the detention/infiltration system. All excavated material from this area will be located downgradient to prevent redeposition of this material in the system during runoff events.
- ◆ *Swales:* Temporary erosion and sediment controls will be utilized during construction. Mulch anchoring will be done immediately after seeding.
- ◆ *Detention Basins:* The detention basins will be inspected immediately after storm events and cleaned to remove sediment buildup. The control structure will be inspected immediately after storm events and cleaned whenever sediment clogs the structure.
- ◆ *Construction Completion:* The entire stormwater management system will be inspected upon completion of construction. Sediment will be removed from the system at this time.

Schedule for Inspection and Maintenance after Construction:

- ◆ *Street sweeping:* Street sweeping will occur at least twice a year, once coinciding with the end of the winter sanding season and once during the late fall.
- ◆ *Catchbasins, Area Drains and Drop Inlets:* The removal of sediments and trash will occur when catchbasins, area drains and drop inlets are cleaned out. At a minimum, catchbasins, area drains and drop inlets will be inspected quarterly and cleaned on a semi-annual basis. Disposal of accumulated sediment will be performed in accordance with applicable local, state and federal guidelines and regulations.
- ◆ *Infiltration System:* After construction, the detention/infiltration system will be inspected after every major storm for the first year to ensure proper function. Thereafter, the system will be inspected twice per year, with cleaning occurring as needed.
- ◆ *Swales:* Swales will be inspected at least semi-annually, and maintenance and repairs made as necessary. Additional inspections will be scheduled during the first few months to make sure the vegetation is adequately established. Repairs and reseeded will be done as required. Swales will be mowed at least once per year. The grass will not be cut too often or shorter than four inches, to maintain the

effectiveness of the swale for pollutant removal and nutrient intake. Sediment and debris will be removed manually, at least once per year, before the vegetation is adversely impacted.

- ◆ *Sediment Forebay:* The sediment forebay located within the detention basins will be inspected and cleaned at least once per year. A 4"x4" wooden marker post will be placed in each basin forebay. If the forebay fills up by 50%, it shall be cleaned. Sediments will be handled and disposed in accordance with local, state and federal guidelines and regulations.
- ◆ *Detention Basin:* Once constructed, the detention basins will be inspected after several storm events to confirm drainage system functions, bank stability, and vegetation growth. Problems will be addressed immediately. During the first six months of operation, the basin will be inspected immediately after significant storm events and cleaned to remove sediment buildup. The control structure will be inspected and cleaned when sediment appears to have clogged the structure. Thereafter, the basin will be inspected annually and sediment will be removed as necessary or at a minimum once every 10 years. At least twice during the growing season, the side slopes will be mowed, and accumulated trash and debris will be removed. Accumulated sediment in forebay will also be removed at this time.
- ◆ The entire stormwater management system, including piping, catchbasins, and manholes will be cleaned prior to final site acceptance. Sediment and debris will be removed and disposed of in accordance with local, state and federal guidelines and regulations.

Snow removal and storage: Snow plowing on the property will be done as winter conditions warrant. Snow will be removed from the paved roadways and parking areas using plows and other equipment, as necessary. Signs designating snow pile areas will be kept in place. Snow storage areas will be located in pervious areas on-site that will promote slow infiltration to prevent ponding and prevent draining directly towards the adjacent wetlands. The snow storage areas will be inspected frequently. Removal of sediment from the snow storage areas will occur every spring.

Ice Melt: Calcium chloride, or a similar ice melt product that does not contain sodium, will be used on paved roadways, parking areas, drives, and walkways on the property.

6.3.7 Floodplain

The project will result in an increase in the 100-year floodplain volume available on site. The construction of a small section of parking area/driveway and portions of three buildings will impact the 100-year floodplain of Little Pond (which outfalls to Little River). In order to bring the grade up in these areas to (construct the driveway and buildings),

approximately 36,809 cubic feet (cf) of the 100-year floodplain will be filled between elevations 5.0 and 9.8 (refer to Figure 4 and Table 10).

In accordance with the Town of Belmont Zoning By-laws, floodplain compensation was provided on a foot-by-foot basis. Compensatory calculations were performed for the project site. Existing and proposed floodplain storage volumes were compared to demonstrate that the proposed site improvements would create a net increase in the 100-year floodplain storage volume available to Little River.

To compensate for the loss in floodplain storage, compensatory storage volume will be created on-site between elevations 5.0 and 9.8, in two areas adjacent to the impacted floodplain (see Figure 5). The compensatory storage areas will be hydraulically connected to the existing floodplain along the northern and southerly portions of the site. This will ensure that during the 100-year storm, water within Little Pond will backflow into the compensatory storage areas. The purpose of the compensatory storage areas is to replicate the existing floodplain and to ensure that the floodplain of Little Pond will continue to function as it does under existing conditions. The compensatory volume will provide a net increase in storage at the same elevations from which existing floodplain storage is being removed.

It should be noted that credit for storage volume within the compensatory storage area was taken only for new floodplain storage volume created at each incremental contour elevation. No credit for compensatory storage was taken for existing floodplain storage volumes.

Tables 10 through 12 summarize the 100-year floodplain (elevation 9.8) impacts and compensatory storage.

Table 10 Impacts to the 100-Year Floodplain

Increment	Area (square feet)	Average Area (square feet)	Cumulative Storage Volume
5.0	0	0	0
6.0	3,117	1,559	1,559
7.0	5,114	4,116	5,675
8.0	8,887	7,001	12,676
9.0	13,636	11,262	23,938
9.8	18,542	12,871	36,809
TOTAL			36,809

Table 11 100-Year Floodplain Compensatory Storage

Increment	Area (square feet)	Average Area (square feet)	Cumulative Storage Volume (cubic feet)
5.0	0	0	0
6.0	3,386	1,693	1,693
7.0	5,791	4,589	6,282
8.0	10,072	7,932	14,214
9.0	16,551	13,312	27,526
9.8	20,319	14,748	42,274
TOTAL			42,274

Table 12 100-Year Floodplain Compensatory Storage Analysis

Increment	Impacts to the Existing 100 year Flood Plain (cubic feet)	Proposed Compensatory Storage (cubic feet)
5.0	0	0
6.0	1,559	1,693
7.0	5,675	6,282
8.0	12,676	14,214
9.0	23,938	27,526
9.8	36,809	42,274
TOTAL	36,809	42,274

To compensate for the loss of floodplain storage of approximately 36,809 cf, approximately 42,274 cf of compensatory storage volume (approximately a 10% increase in available volume) will be created on-site between elevation 5.0 and 9.8. This represents a net increase of approximately 5,465 cf of storage volume.

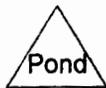

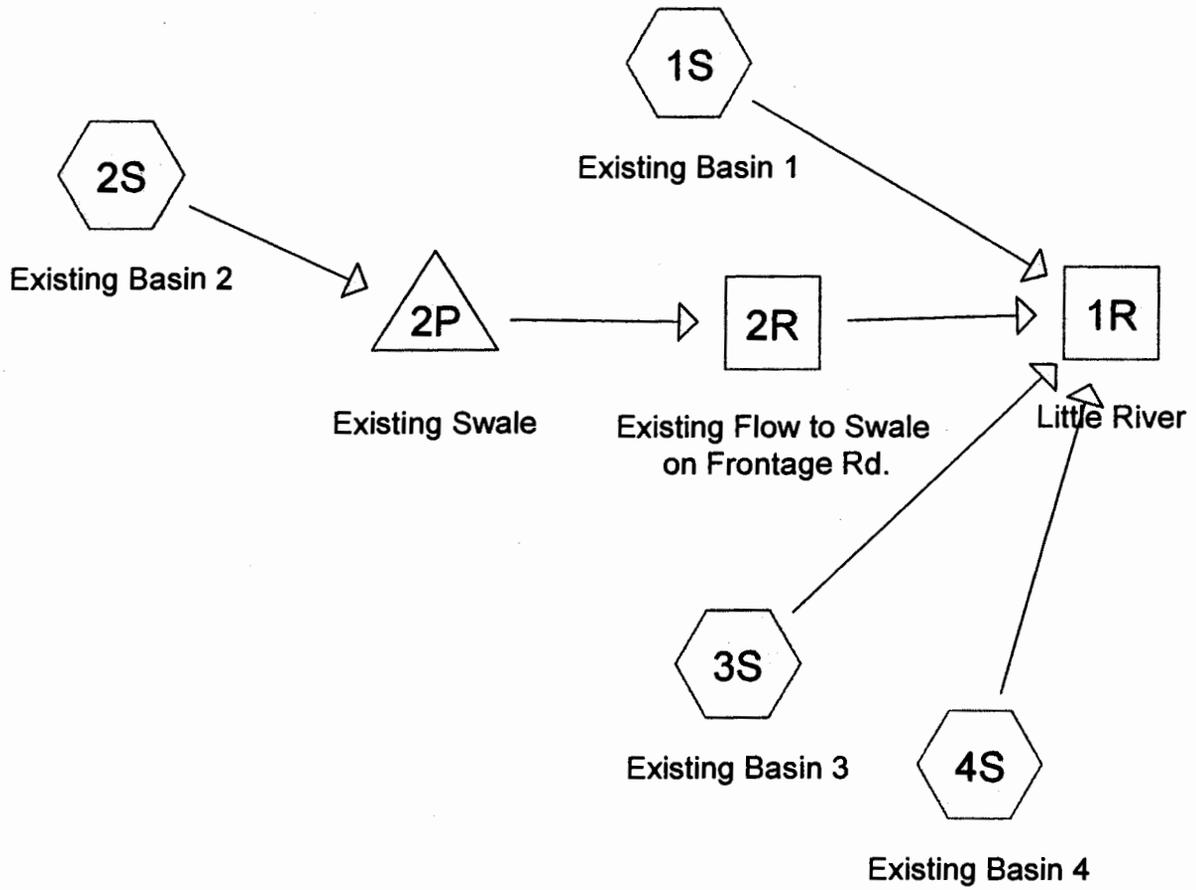

6.3.8 Town of Belmont Zoning By-Laws

The project conforms to the Standards outlined in Section 6B.7-Stormwater Management Facilities of the Town of Belmont Zoning By-Law Amendment (dated May 28, 2002) as described below.

- ◆ The post-development discharge rates for the 2-, 10-, 25- and 100-year storm events do not exceed the pre-development discharge rates.
- ◆ Building roof drainage will be piped directly to an underground infiltration system sized to meet the DEP groundwater recharge requirements for the site.
- ◆ Stormwater runoff from on-site paved areas will be collected and conveyed through deep sump catchbasins and storm drain pipes to adjacent stormwater management systems. The pipe capacity of the storm drain system will be designed to convey the 10-year storm frequency.
- ◆ Proposed detention basin(s) and swale(s) will detain the difference in pre- versus post-development stormwater discharge rates from the site.
- ◆ Proposed detention basin(s) will have adequate storage volume to contain the peak elevation during the 100-year storm event within its top of bank.
- ◆ Compensatory storage volume provided due to loss of floodplain storage of Little River will result in a net increase of 5,465 cf of volume within the 100-year floodplain.
- ◆ Creation of an acceptable Stormwater Facilities Maintenance Plan. Refer to Section 6.3.6.

New development Yes

No

Redevelopment Yes

No

Combination Yes (If yes, distinguish redevelopment components from new development components on plans).

No

Note:
 This February 2000 version of the Stormwater Management Form supersedes earlier versions including those contained in DEP's Stormwater Handbooks.

2. Stormwater runoff to be treated for water quality are based on which of the following calculations:

1 inch of runoff x total impervious area of post-development site for discharge to **critical areas** (Outstanding Resource Waters, recharge areas of public water supplies, shellfish growing areas, swimming beaches, cold water fisheries).

0.5 inches of runoff x total impervious area of post-development site for other resource areas.

3. List all plans and documents (e.g. calculations and additional narratives) submitted with this form:

None. This is not being submitted to the town.

B. Stormwater Management Standards

DEP's Stormwater Management Policy (March 1997) includes nine standards that are listed on the following pages. Check the appropriate boxes for each standard and provide documentation and additional information when applicable.

Standard #1: Untreated stormwater

The project is designed so that new stormwater point discharges do not discharge untreated stormwater into, or cause erosion to, wetlands and waters.

Massachusetts Department of Environmental Protection
 Bureau of Resource Protection - Wetlands
WPA Appendix C – Stormwater Management Form
 Massachusetts Wetlands Protection Act M.G.L. c. 131, §40

B. Stormwater Management Standards (cont.)

Standard #2: Post-development peak discharges rates

Not applicable – project site contains waters subject to tidal action.

Post-development peak discharge does not exceed pre-development rates on the site at the point of discharge or downgradient property boundary for the 2-yr and 100-yr, 24-hr storms.

- without stormwater controls
- with stormwater controls designed for the 24-hr, 2-yr, and 10-yr storms.
- The project's stormwater design will not increase off-site flooding impacts from the 100-yr, 24-hr storm.

Standard #3: Recharge to groundwater

Amount of impervious area (sq. ft.) to be infiltrated: 217,800 sf

Volume to be recharged is based on:

The following Natural Resources Conservation Service hydrologic soils groups (e.g. A, B, C, D, or UA) or any combination of groups:

<u>100%</u>	<u>B</u>		
(% of impervious area)	(Hydrologic soil group)	(% of impervious area)	(Hydrologic soil group)
_____	_____	_____	_____
(% of impervious area)	(Hydrologic soil group)	(% of impervious area)	(Hydrologic soil group)

Site specific pre-development conditions: 0.52 in/hr .062 AC-FT
 Recharge rate Volume

Describe how these calculations were determined:

Refer to Stormwater Management Summary

List each BMP or nonstructural measure used to meet Standard #3. (e.g. dry well, infiltration trench).

4 Underground detention / Infiltration System (1) Retention Basin

(2) Detention Basins (2) Grassed Swales

The annual groundwater recharge for the post-development site approximates the annual recharge from existing site conditions.

Yes

No

Massachusetts Department of Environmental Protection
Bureau of Resource Protection - Wetlands
WPA Appendix C – Stormwater Management Form
Massachusetts Wetlands Protection Act M.G.L. c. 131, §40

B. Stormwater Management Standards (cont.)

Standard #4: 80% TSS Removal

- The proposed stormwater management system will remove 80% of the post-development site's average annual Total Suspended Solids (TSS) load.

Identify the BMP's proposed for the project and describe how the 80% TSS removal will be achieved.

Street Sweeping, deep sump and hooded catchbasins, detention basin, and water quality swales.

If the project is redevelopment, explain how much TSS will be removed and briefly explain why 80% removal cannot be achieved.

N/A

Standard #5: Higher potential pollutant loads

Does the project site contain land uses with higher potential pollutant loads (See Stormwater Policy Handbook – Vol. I, page I-23, for land uses of high pollutant loading).

- Yes If yes, describe land uses: _____
- No

Identify the BMPs selected to treat stormwater runoff. If infiltration measures are proposed, describe the pretreatment. (Note: If the area of higher potential pollutant loading is upgradient of a critical area, infiltration is not allowed.)

Standard #6: Protection of critical areas

Will the project discharge to or affect a critical area? (See Stormwater Policy Handbook – Vol. I, page I-25, for critical areas).

- Yes If yes, describe areas: _____
- No

Identify the BMPs selected for stormwater discharges in these areas and describe how BMPs meet restrictions listed on pages I-27 and I-28 of the Stormwater Policy Handbook – Vol. I:

Massachusetts Department of Environmental Protection
 Bureau of Resource Protection - Wetlands
WPA Appendix C – Stormwater Management Form
 Massachusetts Wetlands Protection Act M.G.L. c. 131, §40

B. Stormwater Management Standards (cont.)

Note:
 components of
 redevelopment
 projects which
 plan to develop
 previously
 undeveloped
 areas do not fall
 under the scope

Standard #7: Redevelopment projects

Is the proposed activity a redevelopment project?

Yes

If yes, the following stormwater management standards have been met:

No

The following stormwater standards have not been met for the following reasons:

The proposed project will reduce the annual pollutant load on the site with new or improved stormwater control.

Standard #8: Erosion/sediment control

Erosion and sediment controls are incorporated into the project design to prevent erosion, control sediments, and stabilize exposed soils during construction or land disturbance.

Standard #9: Operation/maintenance plan

An operation and maintenance plan for the post-development stormwater controls have been developed. The plan includes ownership of the stormwater BMPs, parties responsible for operation and maintenance, schedule for inspection and maintenance, routine and long-term maintenance responsibilities, and provision for appropriate access and maintenance easements extending from a public right-of-way to the stormwater controls.

C. Submittal Requirements

DEP recommends that applicants submit this form, as well as, supporting documentation and plans, with the Notice of Intent to provide stormwater management information for Commission review consistent with the wetland regulations (310 CMR 10.05 (6)(b)) and DEP's Stormwater Management Policy (March 1997). If a particular stormwater management standard cannot be met, information should be provided to demonstrate how equivalent water quality and water quantity protection will be provided. DEP encourages engineers to use this form to certify that the project meets the stormwater management standards as well as acceptable engineering standards. For more information, consult the Stormwater Management Policy.

Groundwater Recharge Calculations

Stormwater Management
Rizzo Associates, Inc.

VOLUME OF GROUNDWATER REQUIRED FOR RECHARGE

TOTAL IMPERVIOUS AREA OVER "D" SOILS - DISREGARD

TOTAL IMPERVIOUS AREA OVER "B" SOILS - 2.79 AC.

$$\begin{aligned} \text{RECHARGE REQUIRED} &= 2.79 \text{ AC.} \times 0.25 \text{ INCH} \times \frac{1 \text{ FT}}{12 \text{ IN}} \\ &= \underline{0.06 \text{ AC./FT.}} \end{aligned}$$

INFILTRATION RATE FOR "B" SOILS - 0.52 IN/HR
(SEE CHART ATTACHED)

INFILTRATION AREA PROVIDED

VOLUME PROVIDED

IC-1 = 30' x 40' x 5'

1833 CF

IC-2 = 50' x 120' x 6'

14,474 CF

IC-3 = 35' x 70' x 5'

5343 CF

IC-4 = 30' x 90' x 6'

11,244 CF

RETENTION BASIN A = 50' x 220' x 3'

21,569 CF

RETENTION BASIN 1 = 150' x 35' x 3'

14,175 CF

RETENTION BASIN 2 = 20' x 90' x 3'

7,459 CF

76,121 CF

INFILTRATION PROVIDED

IC-1 SURFACE AREA = $(30' \times 40') + (40' \times 5' \times 2) + (30' \times 5' \times 2)$
= 1900 SF

INFILTRATION RATE = $1900 \text{ SF} \times .52 \text{ in/hr} \times \frac{1 \text{ ft}}{12 \text{ in}} \times \frac{1 \text{ hr}}{3600 \text{ s}} = \underline{0.02 \text{ cfs}}$

IC-2 SURFACE AREA = $(50' \times 120') + (50' \times 6' \times 2) + (120' \times 6' \times 2)$
= 8040 SF

INFILTRATION RATE = $8040 \text{ SF} \times .52 \text{ in/hr} \times \frac{1 \text{ ft}}{12 \text{ in}} \times \frac{1 \text{ hr}}{3600 \text{ s}} = \underline{0.10 \text{ cfs}}$

IC-3 SURFACE AREA = $(35' \times 70') + (35' \times 5' \times 2) + (70' \times 5' \times 2)$
= 3500 SF

INFILTRATION RATE = $3500 \text{ SF} \times .52 \text{ in/hr} \times \frac{1 \text{ ft}}{12 \text{ in}} \times \frac{1 \text{ hr}}{3600 \text{ s}} = \underline{0.04 \text{ cfs}}$

IC-4 SURFACE AREA = $(90' \times 90') + (90' \times 6' \times 2) + (90' \times 6' \times 2)$
= 9240 SF

INFILTRATION RATE = $9240 \text{ SF} \times .52 \text{ in/hr} \times \frac{1 \text{ ft}}{12 \text{ in}} \times \frac{1 \text{ hr}}{3600 \text{ s}} = \underline{0.11 \text{ cfs}}$

RETENTION BASIN A $(50' \times 120') + (50' \times 5' \times 2) + (120' \times 5' \times 2)$
SURFACE AREA = 6000 SF

INFILTRATION RATE = $6000 \text{ SF} \times .52 \text{ in/hr} \times \frac{1 \text{ ft}}{12 \text{ in}} \times \frac{1 \text{ hr}}{3600 \text{ s}} = \underline{0.07 \text{ cfs}}$

RETENTION BASIN 1 = $(40' \times 35') + (40' \times 3' \times 2) + (35' \times 3' \times 2)$
SURFACE AREA = 630 SF

INFILTRATION RATE = $630 \text{ SF} \times .52 \text{ in/hr} \times \frac{1 \text{ ft}}{12 \text{ in}} \times \frac{1 \text{ hr}}{3600 \text{ s}} = \underline{0.03 \text{ cfs}}$

Groundwater Recharge Calculations
Residences at Acorn Park
Belmont, MA

Design Criteria:

B-soil=0.25"/AC x total impervious area
Infiltration Rate = 0.52 in/hr

Total Impervious Area (Ac)= 2.79

Required Recharge Volume (AF) = 2.79 x .25"/12= 0.058

Recharge Provided from 4 Infiltration Basins (AF) = 0.48 (see HydroCAD)

Recharge Provided from 1 Retention Basin (AF) = 0.14 (see HydroCAD)

Recharge Provided from 2 Detention Basins (AF) = 0.21 (see HydroCAD)

Number based on HydroCad analysis for 2-year storm, will increase with higher storm events.

Drawdown Analysis:

Infiltration Volume =76,121 CF

Infiltration Area = 37,520 SF

Drawdown Rate: 0.52 in/hr X 1/12 x 37,520=1626 CF/HR

V/R=76121/1626=47 Hours

Pond design: 1.0"/AC of pavement area to be treated

6.1 Wastewater Management

6.1.1 Sewer Connection

The sewer connection route for the project consists of installing a small sewer pump station on-site and a 5-inch force main along Acorn Park Drive, Frontage Road, Lake Street and Garrison Road. The force main will connect to the existing Town of Belmont gravity sewer located at the intersection of Garrison Road and Gilmore Road. The Town has plans to replace the downstream 8-inch sewers in Gilmore Road and Oliver Road as part of its infiltration/inflow (I/I) reduction program described below. The proponent will work with the Town to upgrade these sewers to provide additional capacity to accept flow from the proposed project. The proponent will further work with the Town to coordinate the construction of the new sewers required for the project connection with the planned sewer upgrade work to minimize disruption to town streets.
